Capstone Project
Proposal Draft

What are you going to build?

I want to build an enterprise end-to-end platform for collecting, analyzing and acting on anonymized feedback from authenticated sources.

Why is this something you want to build?

I've heard (and felt myself) from multiple clients and coworkers a strong desire to communicate a ton of concerns, process improvements and critical feedback but did not do so. Executives and organization leadership want feedback but many struggle to get it due to privacy concerns and fear of retaliation. This is an organizational communication problem that can be solved by using a combination of several new and existing technologies.

While the target use case for this platform is organizations collecting internal feedback on processes and culture, the core technology could be implemented to allow end users of anything to provide anonymized feedback to parties that seek to collect it.

What are you planning on building for your MVP that's due halfway through the semester?

A MVP of such a platform would include:

- Web based UI for feedback submission
 - Robust AI-based scrambling option
 - AI-driven nudges and auto-edit suggestions
- Authentication without Identity implemented for AAD
 - Other auth providers as stretch goals
 - Truly anonymized submission mechanisms (several steps)
- Middleware layer for storing and reporting anonymized feedback
 - Weekly? batching process
- Executive Dashboard for metrics
 - Suggestions for changes to implement (quarterly)
 - Culture pain points and improvement suggestions
- HR / PeopleOps dashboard for monitoring change adoption and efficacy

Which technologies are you going to use? Why?

I really want to greenfield a project using [bun](#) because of the robust features and performance.

I am dubious about the performance but I would like to implement [Transformers.js](#) for the AI-driven frontend suggestion and scrambling features

Likely just Node or something that plays nicely with a JS frontend (Go/Ruby?) for the backend.

PostgreSQL for structured data storage (Org, feedback, logs, etc...)

[Chart.js](#) for dashboard charting

[OpenTelemetry](#) for accessing app and infrastructure performance
